

Basic server types

Web Server

- Hosts and serves web pages and web applications to clients.
- Handles HTTP requests from web browsers and delivers HTML content.
- Supports various technologies such as PHP, ASP.NET, or Node.js
- Provides security measures like SSL certificates for encrypted communication.

eMail Server

- Facilitates the sending, receiving, and storage of email messages.
- Uses protocols like SMTP, POP3, or IMAP to handle email transfers.
- Stores emails in user mailboxes and allows access through email clients or web interfaces.
- Implements spam filtering, virus scanning, and authentication mechanisms for email security.

Database Server

- Manages and stores structured data, enabling efficient data retrieval and manipulation.
- Supports query languages like SQL for managing and retrieving data.
- Provides features such as data integrity, transaction management, and access control.
- Offers scalability options to handle large amounts of data and concurrent connections.

DNS Server

- Translates domain names (e.g., www.example.com) into IP addresses (e.g., 192.168.1.1).
- Resolves queries from clients, directing them to the appropriate IP address.
- Implements caching to improve query response times and reduce network traffic.
- Supports zone transfers between DNS servers to synchronize and distribute domain records.

File Server

- Centralized storage and management of files for client devices on a network.
- Allows clients to access shared files and folders over a network connection.
- Implements access controls to restrict file permissions and maintain security.
- Supports features like file locking, versioning, and backup to ensure data integrity.

FTP Server

- Enables file transfer between a client and a server using the File Transfer Protocol (FTP).
- Provides user authentication and access control for secure file transfers.
- Supports uploading, downloading, and managing files and directories.
- Can be used for public file distribution or as a private file repository.

Web Proxy Server

- Acts as an intermediary between client devices and web servers.
- Caches frequently requested web content, improving performance and reducing bandwidth usage.
- Provides anonymity and security by masking client IP addresses and filtering web traffic.
- Controls access to specific websites, enforcing content filtering or firewall rules.

DHCP Server

- The Dynamic Host Configuration Protocol (DHCP) enables devices on a network to automatically obtain crucial network settings, such as their IP address, subnet mask, default gateway, and DNS server information, without requiring manual configuration of these parameters.
