

POP3 Protocol v.s. IMAP Protocol

POP3 (Post Office Protocol version 3)

- POP3 uses port 110 for standard connections and port 995 for secure SSL/TLS connections.
- POP3 mainly interacts with the Inbox; server-side folders (like Sent or Archive) typically aren't accessible.
- POP3 is useful for users with limited server storage because it pulls mail off the server.
- Settings vary: some clients delete emails after download, while others keep copies on the server.

VS

IMAP (Internet Message Access Protocol)

- IMAP uses port 143 for standard connections and port 993 for secure SSL/TLS connections.
- IMAP supports server-side folders and labels, so you can organize email the same way across all devices.
- Most modern mail apps and providers recommend IMAP since it's designed for multi-device use.
- IMAP requires an internet connection to view full messages unless your client stores offline copies.
